# Project 1

Topic Modeling in PyMC

# Topic Modeling

- Probabilistic models for uncovering the underlying semantic structure of a document collection based on a hierarchical Bayesian analysis of the original texts
- Topic models are algorithms for discovering the main themes that pervade a large and otherwise unstructured collection of documents. Topic models can organize the collection according to the discovered themes.

### Seeking Life's Bare (Genetic) Necessities

COLD SPRING HARBOR, NEW YORK—How many **genes** does an **organism** need to **survive**? Last week at the genome meeting here,\* two genome researchers with radically different approaches presented complementary views of the basic genes needed for **life**. One research team, using **computer** analyses to compare known **genomes**, concluded that today's **organisms** can be sustained with just 250 genes, and that the earliest life forms required a mere 128 **genes**. The other researcher mapped genes in a simple parasite and estimated that for this organism, 800 genes are plenty to do the job—but that anything short of 100 wouldn't be enough.

Although the numbers don't match precisely, those **predictions**

"are not all that far apart," especially in comparison to the 75,000 **genes** in the human genome, notes Siv Andersson of Uppsala University in Sweden, who arrived at the 800 number. But coming up with a consensus answer may be more than just a **genetic numbers** game, particularly as more and more **genomes** are completely mapped and sequenced. "It may be a way of organizing any newly **sequenced genome**," explains Arcady Mushegian, a **computational** molecular biologist at the National Center for Biotechnology Information (NCBI) in Bethesda, Maryland. Comparing an

## Topic proportions & assignments

# Latent Dirichlet Allocation (LDA)

- In the LDA model, each document is viewed as a mixture of topics that are present in the corpus. The model proposes that each word in the document is attributable to one of the document's topics
- The idea behind LDA is to model documents as arising from multiple topics, where a topic is defined to be a distribution over a fixed vocabulary of terms
- Given a dataset of documents, LDA backtracks and tries to figure out what topics would create those documents in the first place

# LDA: Generative Process

- Suppose,  $M$  is the number of documents in our collection.  $N_m$  is the number of words in the  $m$ -th document and  $V$  the size of the vocabulary.  $K$  is the number of predefined-topics. In this case, the number of topics is not automatically inferred. Instead, we will manually set the value of  $K$  based on our intuition.
- Documents are represented as random mixtures over latent topics, where each topic is characterized by a distribution over all the words

# LDA: Generative Process

For each topic  $k$ , we draw its word distribution, which is denoted as  $\phi_k$ . As prior for the per-topic word distribution we will use a V-dimensional symmetric Dirichlet distribution:

$$\phi_k \sim \text{Dir}(\beta), 1 \leq k \leq K$$

For each document  $m$ , we draw a topic distribution, which is denoted as  $\theta_m$ . As prior for the per-document topic distribution we will use a K-dimensional symmetric Dirichlet distribution:

$$\theta_m \sim \text{Dir}(\alpha), 1 \leq m \leq M$$

The hyperparameters  $\alpha$  and  $\beta$  are assumed to be fixed typically sparse  $\alpha, \beta \leq 1$  (set them to 1)  
For each word  $n$  in document  $d$  (for each of the word positions), we draw a topic for that word according to a Multinomial (Categorical) distribution:

$$z_{m,n} \sim \text{Multinomial}(\theta_m), 1 \leq m \leq M, 1 \leq n \leq N_m$$

Draw the physical word itself from the word distribution associated with its selected topic. Each word is denoted as  $w_{m,n}$ :

$$w_{m,n} \sim \text{Multinomial}(\phi_{z_{m,n}}), 1 \leq m \leq M, 1 \leq n \leq N_m$$

# The Task 1

- Start with a corpus (document collection)
- Build the observed variable:

$$w_{m,n} \quad 1 \leq m \leq M, 1 \leq n \leq N_m$$

- Infer the hidden topic structure:

$$\theta_m \quad 1 \leq m \leq M$$

$$\varphi_k \quad 1 \leq k \leq K$$

**Document 1:** I had a peanuts butter sandwich for breakfast.

**Document 2:** I like to eat almonds, peanuts and walnuts.

**Document 3:** My neighbor got a little dog yesterday.

**Document 4:** Cats and dogs are mortal enemies.

**Document 5:** You mustn't feed peanuts to your dog.

# The Task 2

- Can the topic model be used to define a topic-based similarity measure between documents?
- What about a new document? How can topics be assigned to it?
